

Growth site requirements

Blackberries do not require any particular type of soil, but they do prefer medium-heavy soil that drains well and is slightly acidic. They do not tolerate compact and soggy soils. They thrive in sunny spots sheltered from the wind. How susceptible they are to frost depends on the variety and growth site. When planted in a favourable site (sunny, sheltered from the wind), blackberries can be cultivated at up to 800 m above sea level. In very low temperatures and areas prone to late frost, winter protection for the plants is recommended.

Planting depth

The plants must be placed deep enough in the ground so that the upper rim of the root ball is covered with 2 cm of earth.

Watering requirements

Before planting, make sure the root balls have been thoroughly soaked. Once planted, make sure the area around the roots remains sufficiently moist, particularly during the initial growth phase.

Please note:

The use of plastic film increases the risk of vole infestation. Take preventive action in good time!
